

Chapter 3 — Conditional Statements

Original educational notes prepared as sample source material for the RAG assignment.

Decision Making

Conditional statements allow a program to choose different actions depending on whether a condition is true or false. Python uses `if`, `elif`, and `else` for this purpose.

if Statement

An `if` statement runs its indented block when its condition evaluates to `True`. Example: `if age >= 18:` followed by an indented `print` statement.

elif and else

The `elif` statement checks another condition when earlier conditions were false. The `else` block runs when none of the preceding conditions are true. Multiple `elif` blocks can be used.

Comparison and Logical Operators

Comparison operators include `==`, `!=`, `<`, `>`, `<=`, and `>=`. Logical operators include `and`, `or`, and `not`. They can be combined to create more specific conditions.
