

Chapter 5 — Functions

Original educational notes prepared as sample source material for the RAG assignment.

What is a Function?

A function is a reusable block of code designed to perform a specific task. Functions help organize programs and reduce repeated code.

Defining a Function

Python functions are defined with the `def` keyword. Example: `def greet(name):` followed by an indented statement such as `print(f"Hello, {name}!")`.

Parameters and Arguments

A parameter is a variable listed in a function definition. An argument is the value supplied when the function is called. Functions can accept multiple parameters.

Return Values

The `return` statement sends a value back to the code that called the function. A function can return numbers, strings, collections, or other Python objects. If a function reaches the end without returning a value, it returns `None`.
